

Context

Dual-layer memory architecture: Supermemory for long-term memory, Rowboat Data Layer for active agent execution.

Overview

The Context System forms Vibemind's memory architecture with a clear two-part division:

1. **Supermemory** — The application's long-term memory. Stores all application data in a memory graph: user behavior, preferences, interaction patterns, and activities across all sessions. Supermemory gives Vibemind a memory of the user and everything that happens in the application.
2. **Rowboat Data Layer** — The active execution data layer. Used by agents in real-time to deliver more accurate and context-specific results. Contains business data, project context, and operational information that agents need for their current work.

This separation ensures that agents have access to both long-term knowledge (Supermemory) and current execution data (Rowboat) — Vibemind operates as a coherent system rather than isolated modules.

Key Features & Contents

- **Supermemory (Long-term Memory):** Memory graph of all application data — user interactions, preferences, usage patterns, content relationships, and behavioral signals for personalized responses and adaptive system behavior
- **Rowboat Data Layer (Execution Data):** Active data layer for agent work — business data, project architecture, dependencies, and operational context that agents use in real-time for more accurate results
- **Session Continuity:** Cross-session state preservation ensuring that learning and context carry forward across user sessions without requiring re-initialization
- **Semantic Indexing:** Relationship mapping between concepts, files, and user interactions to enable contextual retrieval and inference
- **Privacy-Aware Storage:** Context designed for local-first storage with privacy considerations; formal GDPR certification planned

Current Status

- **Coding Context:** Functional and actively used by coding.space for project understanding and state maintenance
- **Supermemory:** Core memory retention and pattern matching operational; advanced contextual inference capabilities in refinement
- **Integration:** Currently connected to coding.space and the main UI_Multiverse; integration with additional spaces in progress

Roadmap

- **Phase 1** (Q2 2026): Implement semantic compression to optimize storage efficiency for long-term memory retention
- **Phase 2** (Q3 2026): Develop context querying interface allowing users to inspect and manage their stored context and memory
- **Phase 3** (Q4 2026): Enable cross-platform context synchronization for unified experience across desktop and web interfaces
- **Phase 4** (2027): Implement temporal context snapshots for historical analysis and pattern evolution tracking

Ecosystem Fit

The Context folder is the epistemic foundation of Vibemind. Every space relies on shared context to operate effectively. By maintaining this central knowledge layer, Vibemind eliminates information silos and enables the platform's defining feature: truly coordinated multi-agent operation where different specialized agents understand the broader system state and user intent. Without this layer, Vibemind would be a collection of independent tools; with it, it becomes an integrated intelligence augmentation platform.

Investment Perspective: Context and memory management are critical infrastructure for AI assistant platforms at scale. This implementation positions Vibemind as a platform that learns and improves with use, creating natural moats through accumulated user data and personalized system behavior. The architecture supports enterprise deployments where multiple users and spaces need coordinated context management.
